Build and debug, together in space.

You and an AI agent inhabit the same engineering workspace. Talk, point, inspect what changes, and verify the result together.

From a failure to a verified fix

Chat, code and logs are often separate. Kineframe brings the investigation into one place, so the developer can understand and steer work while it happens.

FIRST USERS

App developers

Debug agent-built software

Platform engineers

Investigate service failures

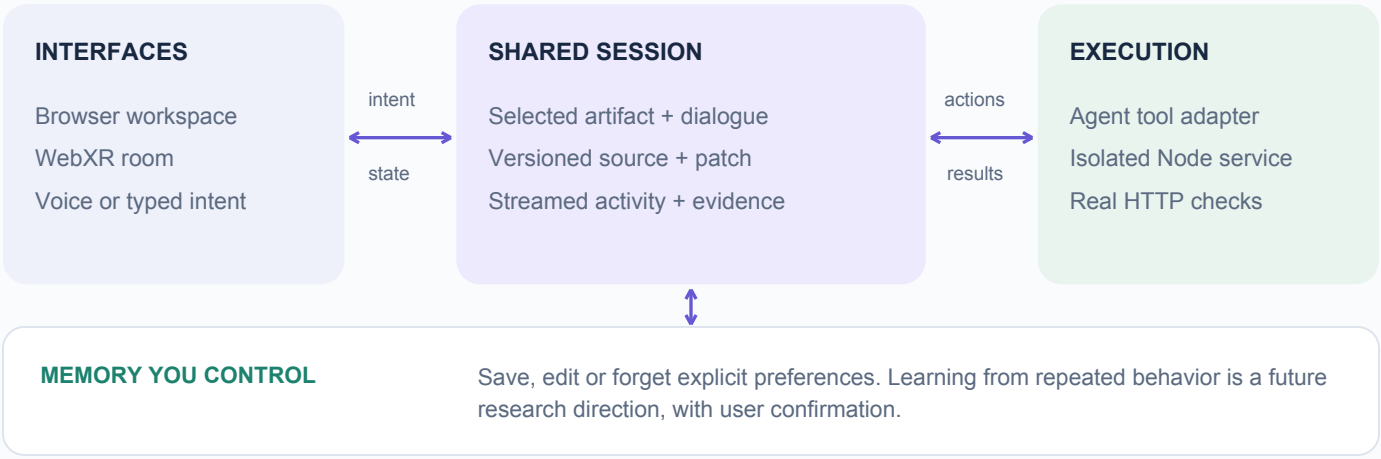

XR teams

Build spatial experiences

A room with a working engine.

Spatial interaction is the interface. Versioned actions and real execution make the collaboration useful.

HOW A SESSION WORKS

WORKING PROTOTYPE

A real, bounded debugging loop.
Reproduce a connection leak or timeout, inspect a proposed source patch, apply it, verify with HTTP requests, and rewind.

Shared activity, explicit memory and turn-based voice. Optional hosted AI; a labeled playbook runs without an API key.

NEXT TO PROVE

Broader software engineering.
Connect arbitrary repositories and infrastructure. Add deeper tool integrations, durable team sessions and confirmed behavioral preferences.

Test headset ergonomics and real-time conversation. Productivity gains and customer demand remain unproven.

THE VALIDATION PLAN

Compare the same debugging task in a conventional agent workflow, Kineframe desktop and VR. Measure time to a verified fix, missed errors, understanding and repeat use. A possible business model is engineering seats plus execution usage.

THE OPPORTUNITY

Visual agents and voice-driven VR coding already exist. The thesis is a complete shared build-and-debug loop: attention, intervention, review, verification and inspectable memory.

Precedents: Cursor Design Mode / DreamCodeVR / Meta Immersive Web SDK / SPHERE. Working name is provisional.
